Motivation

Salient features of the process of economic development:

Capital accumulation **Productivity growth** **Sectorial reallocation**

sectors use different capital types → produced by other sectors or imported

Investment Network

Hirschman ('58)'s hypothesis: investment linkages important for economic development

Motivation

Salient features of the process of economic development:

Capital accumulation **Productivity growth** **Sectorial reallocation**

sectors use different capital types → produced by other sectors or imported

Investment Network

Hirschman ('58)'s hypothesis: investment linkages important for economic development

What is the role of investment network for income disparities?

This paper

1. **Model**: dynamic multisector open economy + **investment network** + IO
   - GDP elasticity to sectoral productivity = $\underbrace{\text{on impact}}_{\text{Hulten}} + \underbrace{\text{capital deepening}}_{\text{transition+LR}}$

2. New harmonized estimates of **cross-country investment networks**
   - Methodology: ≈ BEA in the US
   - Coverage: 58 countries w/income per capita \$428 and \$81599 constant ppp USD
     9 from sSA; 20 with time series from 1960s.

3. **Sectoral influence** and its channels along the development spectrum

4. Role of the investment network for **income disparities**
   - Development accounting
   - Transition dynamics (Korea 1965–2014)

Main findings

Theory:

- **1SGM mis-specified** when investment technology ≠ consumption goods technology
  - MPK depends on productivity ⟶ can't separate technology from capital
- **Sectoral influence**: $\frac{d\ln(GDP)}{d\ln(a)}$ = impact + capital deepening + gross return on capital
  - Domar weights depend on investment rates ⟶ on the whole transition path

Quantitatively:

- **CONS & DUR**: influence via capital deepening, hump-shaped;
  ICT rises w/ income through all channels.
- *Accounting*: Ω disparities account for ≈40% of income variance.
- *Transitions:* **MANUF TFP** key along Korea's growth miracle 1965–2014. relative prices ⟶ only part of the investment network shift

Contribution

1. Sectoral influence with durable goods: on impact vs. capital deepening; Domar weights depend on investment dynamics

   non-durables: Hulten (1978); Acemoglu et.al. (2012), Baqaee & Fahri (2020), Liu (2019), Bigio & La'O (2020)
   long-run comparisons: Baqaee & Malmberg (2025)
   medium-term:: Ho, Lashkari, Sarte (2026)

2. First measures of sectoral investment demand along the development spectrum

   - Evidence of shifts in the composition of investment Garcia-Santana, et.al. 2021; Herrendorf, et.al. 2021
   - Shifts in the demand for investment and (VA) structural change Caunedo & Keller, 2023

   US and in OECD countries → not harmonized vomLehn & Winberry, 2022 and Ding, 2023
   Firm-to-firm transactions (Chile): only domestic Gillmore et. al., 2025

3. Role of the investment network for cross-country income differences: Buera & Trachter (2024)

   IO linkages: Ciccone (2002); Jones (2011); Fadinger, et.al. (2022)

Outline

1. Simple (toy) economy
2. Multisector model: channels of sectoral influence
3. Measurement of the investment network
4. Sectoral influence along the income spectrum
5. Implications for economic development

Fixing ideas

A simple economy

A simple economy

Two sectors, no intermediate inputs, no trade, same output elasticities

- Sectoral technologies

$$y_{it} = z_i K_{it}^{\alpha} L_{it}^{1-\alpha} \qquad z_1 \neq z_2$$

$$y_{it} = c_{it} + \overbrace{\sum_j x_{ijt}}^{x_{it}}$$

A simple economy

Two sectors, no intermediate inputs, no trade, same output elasticities

- Sectoral technologies

$$v_{it} = z_i K_{it}^{\alpha} L_{it}^{1-\alpha} \qquad z_1 \neq z_2$$

$$v_{it} = c_{it} + \overbrace{\sum_j x_{ijt}}^{x_{it}}$$

- Capital accumulation

$$K_{it+1} = (1-\delta)K_{it} + \prod_j x_{jit}^{\omega_j}$$

implication: same investment aggregator $\rightarrow p_i^k = p_j^k \rightarrow \frac{K_i}{L_i} = \frac{K}{L}$

- GDP: $\ln(v_t) = \sum_i \tilde{\eta}_{it} \ln(v_{it})$ for $\tilde{\eta}_i$ the expenditure share of sector i

A simple economy: steady state

Two sectors, no intermediate inputs, no trade, same output elasticities

Output per worker

$$\ln(v) = \frac{1}{1-\alpha} \sum_{i=1,2} \tilde{\eta}_i \left(\ln z_i + \ln(\tilde{\eta}_i)\right) + \frac{\alpha}{1-\alpha} \ln\left(\frac{K}{v}\right)$$

where is the investment network?

A simple economy: steady state

Two sectors, no intermediate inputs, no trade, same output elasticities

Output per worker

$$\ln(v) = \frac{1}{1-\alpha} \sum_{i=1,2} \tilde{\eta}_i \left(\ln z_i + \ln(\tilde{\eta}_i)\right) + \frac{\alpha}{1-\alpha} \ln(\frac{K}{v})$$

where is the investment network? 1SGM ($\omega = \tilde{\eta}$):

$$\text{MPK} \equiv \alpha \frac{v}{K}$$

A simple economy: steady state

Two sectors, no intermediate inputs, no trade, same output elasticities

Output per worker

$$\ln(\nu) = \frac{1}{1-\alpha} \sum_{i=1,2} \tilde{\eta}_i \left(\ln z_i + \ln(\tilde{\eta}_i)\right) + \frac{\alpha}{1-\alpha} \ln\left(\frac{K}{\nu}\right)$$

where is the investment network? General ($\omega \neq \tilde{\eta}$):

$$\text{MPK} \equiv \alpha \frac{\nu}{K} \prod_j z_j^{\omega_j - \tilde{\eta}_j} \prod_j \frac{\omega_j^{\omega_j}}{\tilde{\eta}_j^{\tilde{\eta}_j}}$$

- $\omega_j > \tilde{\eta}_j$: $z_j \uparrow \Rightarrow \frac{K}{\nu} \uparrow$ $\quad$ $\omega_j < \tilde{\eta}_j$ (e.g. services): $z_j \uparrow \Rightarrow \frac{K}{\nu} \downarrow$

A simple economy: steady state

Two sectors, no intermediate inputs, no trade, same output elasticities

Output per worker

$$\ln(\nu) = \frac{1}{1-\alpha} \sum_{i=1,2} \tilde{\eta}_i \left(\ln z_i + \ln(\tilde{\eta}_i)\right) + \frac{\alpha}{1-\alpha} \ln\left(\frac{K}{\nu}\right)$$

solving for equilibrium $\frac{K}{\nu}$

$$\ln(\nu) = \sum_j \Bigg(\underbrace{\tilde{\eta}_j}_{\text{on impact}} + \underbrace{\frac{\alpha\,\omega_j}{1-\alpha}}_{\text{capital deepening}} \Bigg) \ln z_j + \text{const.}$$

- without heterogeneity in factor shares $\omega_j \rightarrow$ sectorial influence, not aggregate.
- with heterogeneous $\alpha \rightarrow \Omega$ matters

Multisector Model

of Investment Linkages

The Model

- N sectors, CRS technologies in capital k, labor l and intermediate inputs m

$$\underbrace{y_{nt}}_{\text{gross output}} = G_n(v_{nt}, m_{nt}), \qquad \underbrace{v_{nt}}_{\text{value added}} = z_{nt} V_n(k_{nt}, l_{nt}), \qquad m_{nt} = M_n(m_{1nt}, \ldots, m_{Nnt})$$

  shares: γ_n VA in gross output, α_n capital in VA, $\mu_{in} \rightarrow$ IO matrix M

- Sectors produce for final uses c, intermediates m and domestic investment, χ^d

$$y_{nt} = c_{nt} + \sum_i m_{nit} + \sum_i \chi^d_{nit}$$

- Non-Homothetic CES final output aggregator

$$\sum_{n=1}^{N} \theta_n^{\frac{1}{\sigma}} (c_{nt})^{\frac{\sigma-1}{\sigma}} Y_t^{\frac{\epsilon_n - 1}{\sigma}} = Y_t^{\frac{\sigma-1}{\sigma}}, \qquad Y_t = C_t + \underbrace{e_t}_{\text{exports}}$$

- Small open economy: exports final goods for imported investment goods; balanced trade

The Model

- Sector-specific capital with standard law of motion

$$k_{nt+1} = x_{nt} + (1 - \delta_n)k_{nt}$$

- CRS investment aggregator

$$x_{nt} = X_n(\chi_{1nt}, \ldots, \chi_{Nnt}) \quad \rightarrow \quad \text{Investment network, } \Omega, \text{ w/ } \omega_{in} \equiv \frac{p_i^\chi \chi_{in}}{p_n^x x_n}, \ \sum_i \omega_{in} = 1$$

quantitative: CES, $\omega_{in} = \tilde{\omega}_{in} \left(\frac{p_i^\chi}{p_n^x} \right)^{1-\iota}$

- Investment goods produced domestically or imported

$$\chi_{int} = \underbrace{\left(\frac{\chi_{int}^d}{1-\phi_i}\right)^{1-\phi_i}}_{\text{domestic}} \underbrace{\left(\frac{\chi_{int}^f}{\phi_i}\right)^{\phi_i}}_{\text{imported}}$$

terms of trade: $\mathcal{T}_i \equiv \frac{p}{p_i^f}$

AGP trade

Domar weights

Proposition (Domar weights)

$$\tilde{\eta}_t = \Big[I - \underbrace{(I-\phi)\Omega_t \Gamma_t \alpha_t \rho_t}_{\textit{investment links}} - \underbrace{M_t(I-\Gamma_t)}_{\textit{IO links}} \Big]^{-1} \underbrace{\tilde{\zeta}_t}_{\textit{final uses}} \qquad \rho_{nt} \equiv \frac{p^x_{nt} x_{nt}}{R_{nt} k_{nt}} = \frac{x_{nt}/k_{nt}}{r^x_{nt} + \delta_n}$$

- ρ: investment expenditure relative to capital income
- Domar weights depend on investment rates $\longrightarrow$ on the entire future path

  novel to durable inputs; absent with non-durable inputs
- All the dynamics is in $\rho_{nt} \equiv \frac{p^x_{nt} x_{nt}}{R_{nt} k_{nt}} = \frac{k_{nt+1}/k_{nt} - (1-\delta_n)}{r^x_{nt} + \delta_n} = \frac{g^k_t + \delta_n}{r^x_{nt} + \delta_n}$
- At the Phelps golden rule, $r^x_{nt} = g^k_t$ the network is irrelevant!

welfare

Impact of productivity on GDP

Proposition (GDP)

$$\ln(\nu_t) = \underbrace{\Phi_t \eta_t}_{\text{sectoral influence}} \left[\Gamma_t \ln z_t + \underbrace{\Gamma_t \alpha_t \Omega_t' \phi \ln \mathcal{T}_t}_{\text{terms of trade}} + \underbrace{\Gamma_t \alpha_t (\ln \rho_t - \ln \xi_t)}_{-\alpha \ln(R/p^x)} \right] + \underbrace{\Phi_t \rho_t}_{\text{curvature}}$$

Impact of productivity on GDP

Proposition (GDP)

$$\ln(v_t) = \underbrace{\Phi_t \eta_t}_{\text{sectoral influence}} \Big[\Gamma_t \ln z_t + \underbrace{\Gamma_t \alpha_t \Omega_t' \phi \ln \mathcal{T}_t}_{\text{terms of trade}} + \underbrace{\Gamma_t \alpha_t (\ln \rho_t - \ln \xi_t)}_{-\alpha \ln(R/p^x)} \Big] + \underbrace{\Phi_t \rho_t}_{\text{curvature}}$$

$$\eta_t = \underbrace{\zeta_t'}_{\text{final-demand share}} \underbrace{\left[I - \Gamma_t \alpha_t \Omega_t' (I - \phi) - (I - \Gamma_t) M_t' \right]^{-1}}_{\text{augmented Leontief inverse, } \Xi_t} \qquad \underbrace{\Phi_t \equiv \left(1 - \eta_t \Gamma_t \alpha_t \Omega_t' \phi \mathbf{1} \right)^{-1}}_{\text{trade amplification}}$$

for z sectoral TFP, α capital share, Γ VA share, $(1 - \phi)$ domestic investment share, $\xi = x/k$; ρ: curvature & labor share

Influence vs. Domar weights

$$\underbrace{\eta_t}_{\text{influence}} = \underbrace{\tilde{\eta}_t'}_{\text{Domar}} + \underbrace{\tilde{\eta}_t' \Gamma_t \alpha_t \Omega_t' (I - \phi) \Xi_t}_{\text{productivity built into others' capital}}$$

- Influence ≠ Domar weight because capital is produced
- Investment network enters through capital deepening only
- Large for sectors that supply capital to large, capital-intensive buyers

Channels of sectoral influence

$$\ln(\nu_t) = \underbrace{\tilde{\eta}_t' \Gamma_t \ln z_t}_{\text{on impact}} + \underbrace{\left[\overbrace{\tilde{\eta}_t' \Gamma_t \alpha_t \Omega_t' (I - \phi) \Xi_t \Gamma_t}^{\text{domestic } \Delta k} + \overbrace{(\Phi_t - 1)\eta_t \Gamma_t}^{\text{imported } \Delta k}\right] \ln z_t + \overbrace{\text{TOT}_t}^{\text{terms of trade}}}_{\text{capital deepening}}$$

$$+ \underbrace{\Phi_t \eta_t \Gamma_t \alpha_t (\ln \rho_t - \ln \xi_t)}_{\text{transition}} + \underbrace{\Phi_t \rho_t}_{\text{curvature, labor share}}$$

Channels of sectoral influence

$$\ln(\nu_t) = \underbrace{\tilde{\eta}_t' \Gamma_t \ln z_t}_{\text{on impact}} + \underbrace{\Big[\overbrace{\tilde{\eta}_t' \Gamma_t \alpha_t \Omega_t' (I - \phi) \Xi_t \Gamma_t}^{\text{domestic } \Delta k} + \overbrace{(\Phi_t - 1)\eta_t \Gamma_t}^{\text{imported } \Delta k}\Big] \ln z_t + \overbrace{TOT_t}^{\text{terms of trade}}}_{\text{capital deepening}}$$

$$+ \underbrace{\Phi_t \eta_t \Gamma_t \alpha_t (\ln \rho_t - \ln \xi_t)}_{\text{transition}} + \underbrace{\Phi_t \rho_t}_{\text{curvature, labor share}}$$

Channels of sectoral influence

$$\ln(\nu_t) = \underbrace{\tilde{\eta}_t' \Gamma_t \ln z_t}_{\text{on impact}} + \underbrace{\Big[\overbrace{\tilde{\eta}_t' \Gamma_t \alpha_t \Omega_t' (I - \phi) \Xi_t \Gamma_t}^{\text{domestic } \Delta k} + \overbrace{(\Phi_t - 1)\eta_t \Gamma_t}^{\text{imported } \Delta k}\Big] \ln z_t + \overbrace{TOT_t}^{\text{terms of trade}}}_{\text{capital deepening}}$$

$$+ \underbrace{\Phi_t \eta_t \Gamma_t \alpha_t (\ln \rho_t - \ln \xi_t)}_{\text{transition}} + \underbrace{\Phi_t \rho_t}_{\text{curvature, labor share}}$$

Channels of sectoral influence

$$\ln(\nu_t) = \underbrace{\tilde{\eta}_t' \Gamma_t \ln z_t}_{\text{on impact}} + \underbrace{\Big[\overbrace{\tilde{\eta}_t' \Gamma_t \alpha_t \Omega_t' (I - \phi) \Xi_t \Gamma_t}^{\text{domestic } \Delta k} + \overbrace{(\Phi_t - 1)\eta_t \Gamma_t}^{\text{imported } \Delta k}\Big] \ln z_t + \overbrace{\text{TOT}_t}^{\text{terms of trade}}}_{\text{capital deepening}}$$

$$+ \underbrace{\Phi_t \eta_t \Gamma_t \alpha_t (\ln \rho_t - \ln \xi_t)}_{\text{transition}} + \underbrace{\Phi_t \rho_t}_{\text{curvature, labor share}}$$

Channels of sectoral influence

$$\ln(\nu_t) = \underbrace{\tilde{\eta}_t' \Gamma_t \ln z_t}_{\text{on impact}} + \underbrace{\Big[\overbrace{\tilde{\eta}_t' \Gamma_t \alpha_t \Omega_t' (I - \phi) \Xi_t \Gamma_t}^{\text{domestic } \Delta k} + \overbrace{(\Phi_t - 1)\eta_t \Gamma_t}^{\text{imported } \Delta k}\Big] \ln z_t + \overbrace{\text{TOT}_t}^{\text{terms of trade}}}_{\text{capital deepening}}$$

$$+ \underbrace{\Phi_t \eta_t \Gamma_t \alpha_t (\ln \rho_t - \ln \xi_t)}_{\text{transition}} + \underbrace{\Phi_t \rho_t}_{\text{curvature, labor share}}$$

Channels of sectoral influence, sector j: domestic Δk

$$\underbrace{\gamma_j \sum_i \tilde{\eta}_i \gamma_i \alpha_i}_{\text{i's capital income}} \sum_l \underbrace{\omega_{li}}_{\text{l in i's invest.}} \underbrace{(1-\phi_l)}_{\text{domestic}} \underbrace{z_j}_{\text{in cost of l}} \underbrace{\Xi_{lj}}$$

- $z_j \uparrow \rightarrow$ goods l cheaper (directly if $l = j$, or via IO & investment chains) $\rightarrow$ buyers i that invest in l accumulate k
- Direct term ($\Xi_{lj} \approx \mathbf{1}\{l = j\}$):

$$\gamma_j (1-\phi_j) \sum_i \tilde{\eta}_i \gamma_i \alpha_i \, \omega_{ji}$$

  $\rightarrow$ j as a capital supplier, weighted by buyers' capital income

- Toy economy (steady states, $\gamma = 1$, $\phi = 0$, common ω): $\dfrac{\alpha\,\omega_j}{1-\alpha}$

Channels of sectoral influence, sector j: transition

$$\underbrace{-\Phi \sum_i \eta_i \gamma_i \alpha_i \frac{\partial \ln \left(R_{it}/p^x_{it}\right)}{\partial \ln z_j}}_{\text{transition: gross return on capital}}$$

- k_{it} predetermined $\longrightarrow$ gross return jumps, offsets capital deepening on impact
- Falls back as k accumulates; $\longrightarrow 0$ along the AGP. r − g
- Gross return

$$\frac{R_{it}}{p^x_{it}} = r^x_{it} + \delta_i = \frac{\xi_{it}}{\rho_{it}}, \qquad \xi_{it} = g^k_{it} + \delta_i$$

- No arbitrage:

$$1 + r^x_{i,t+1} = (1 + r_{t+1}) \frac{p^x_{it}}{p^x_{i,t+1}}$$

Cross-Country Investment Networks

Methodology

Methodology

Use Tables (World IO Database): capital produced or imported

How is capital produced/imported by a sector purchased by other sectors?

- Imputation approach ≈ BEA's methodology in the US:
  1. manual allocation
  2. proportional to occupational composition of the sector
  3. proportional to capital expenditures (handful of sectors w/microdata)

Equipment Sectors

- Tools used on the job (Caunedo et.al.,'23)

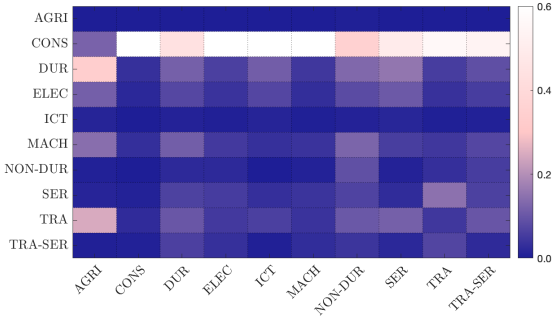

Other Sectors

- Assign capital proportional to intermediate inputs

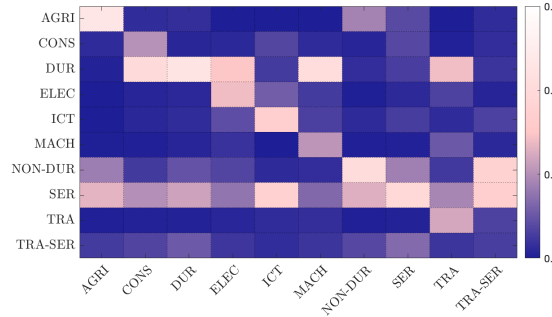

example data coverage

Investment Network vs IO Network 2014

Investment Network along Development

INV Network: India

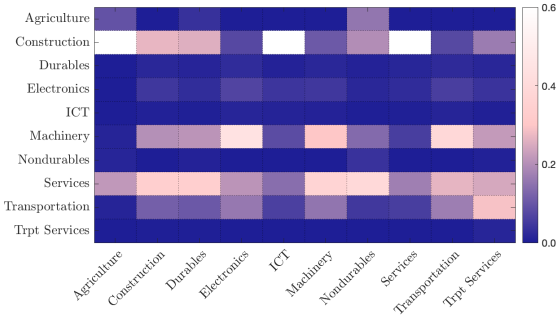

INV Network: USA

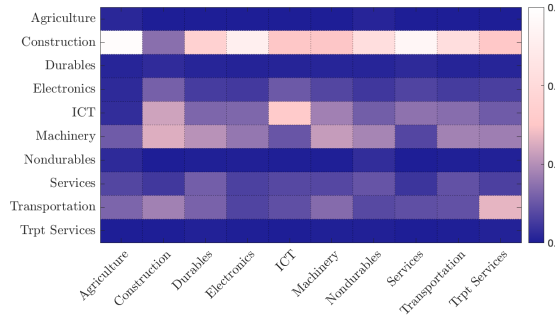

validation vLW | relative prices | validation Chile | outdegrees | HHI demand

Investment Network along Development: South Korea

1965 (GDP p/cap. 1450)

2014 (GDP p/cap. 35524)

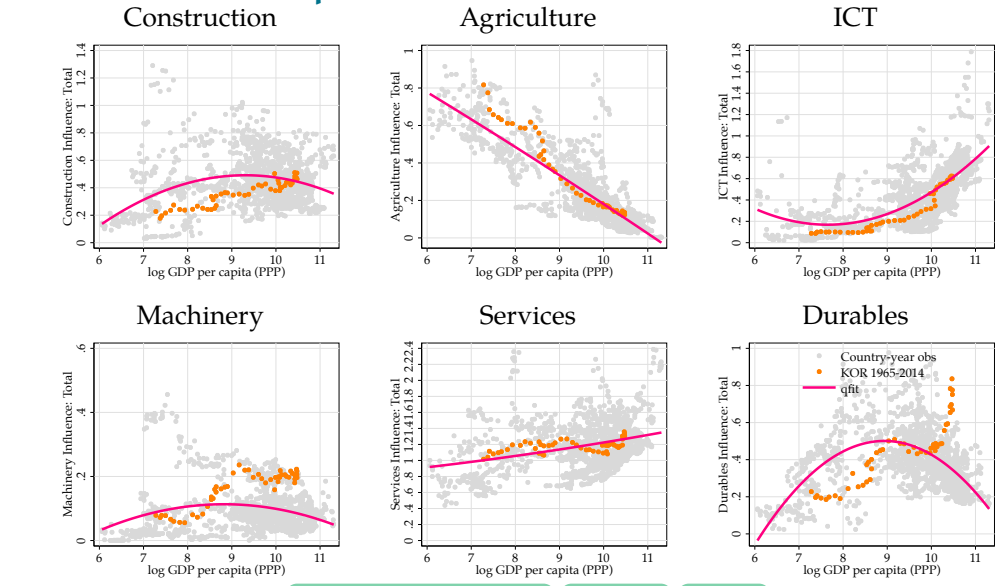

CONS prominent throughout; ICT↑, SERV↓; bundles diversify with income

Sectoral Influence

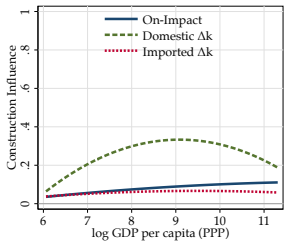

along the development spectrum

Sectoral Influence: $\Phi\eta\Gamma$

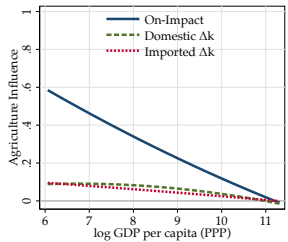

Channels of Sectoral Influence along Development

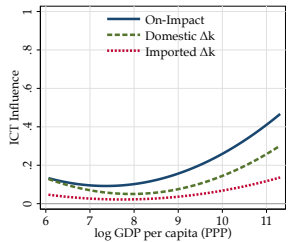

Construction

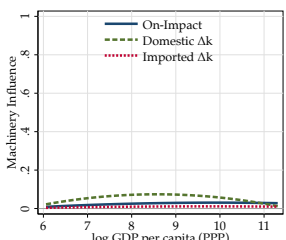

Agriculture

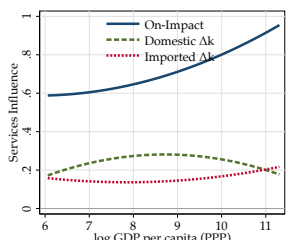

ICT

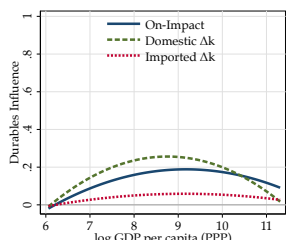

Machinery

Services

Durables

other sectors

Channels of Sectoral Influence: Takeaways

- **CONS**: influence is mostly domestic capital deepening; hump-shaped, peaks at middle income
- **DUR**: capital deepening ≈ on impact; both hump-shaped
- **ICT**: rises with income through all three channels; imported Δk grows at high income
- **AGRI**: on impact only, falls with development (structural change)
- **SERV**: on impact dominates and rises; sizable capital deepening (domestic & imported)

→ capital deepening is where Ω matters: sectors' role as capital suppliers, not their size

Development Accounting

Quantitative Exercises

1. Infer sectoral productivity-like shifters to match observed sectoral value added,
   $\mathfrak{a} = (\Phi\Xi)^{-1} \ln(\mathbf{v}), \quad \mathfrak{a} \equiv \Gamma \ln \mathbf{z} + \Gamma\alpha\Omega'\phi \ln \mathcal{T}$

2. To interpret residuals as productivity:
   common technology in a sector across countries + Hicks neutral productivity.

$$\ln(v_j^c) = \ln z_j^c + h_j(\ln k_j^c, \ln l_j^c, \ln m_j^c)$$

3. How much of the disparities in income per capita come from Ω?

   - when model-predicted output disparities come only from Ω
   - when sectoral productivity interact with Ω
   - when capital intensity is the same across countries
   - when only domestic investment flows are considered

What is the role of Ω for income variance?

Table 1: Development Accounting

	Income Variance	Contribution of Ω
Baseline	1	
Investment Links	0.42	42%

$$\ln(\boldsymbol{\nu}) = \underbrace{\Phi}_{\substack{\text{trade} \\ \text{amplification}}} \quad \underbrace{\zeta'}_{\text{final-demand share}} \quad \underbrace{(I - \Gamma\alpha\Omega'(I - \phi) - (I - \Gamma)M')^{-1}\,\Gamma\mathbf{a}}_{\substack{\text{augmented} \\ \text{Leontief inverse}}}$$

$\longrightarrow$ **42%** of GDP p/cap. variance explained by $\neq$ in the investment network

What is the role of Ω for income variance?

Table 2: Development Accounting

	Income Variance	Contribution of Ω
Baseline	1	
Investment Links	0.42	42%
Investment Links + productivity$_{US}$	0.41	41%

$$\ln(\nu) = \underbrace{\Phi}_{\text{trade amplification}} \quad \underbrace{\zeta'}_{\text{final-demand share}} \quad \underbrace{(I - \Gamma\alpha\Omega'(I-\phi) - (I-\Gamma)M')^{-1}}_{\text{augmented Leontief inverse}} \Gamma a_{US}$$

$\rightarrow$ $\approx$**98%** of investment links contribution explained by $\neq$ in influence

What is the role of Ω for income variance?

Table 3: Development Accounting

	Income Variance	Contribution of Ω
Baseline	1	
Investment Links	0.42	42%
Investment Links + productivity$_{US}$	0.41	41%
Investment Links + α avg.	0.62	62%

$$\ln(\boldsymbol{\nu}) = \underbrace{\Phi}_{\substack{\text{trade} \\ \text{amplification}}} \quad \underbrace{\zeta'}_{\text{final-demand share}} \quad \underbrace{(I - \Gamma\alpha\Omega'(I - \phi) - (I - \Gamma)M')^{-1}}_{\substack{\text{augmented} \\ \text{Leontief inverse}}} \Gamma\mathbf{a}$$

$\longrightarrow$ Δ Capital-intensity dampens the role of Ω.

What is the role of Ω for income variance?

Table 4: Development Accounting

	Income Variance	Contribution of Ω
Baseline	1	
Investment Links	0.42	42%
Investment Links + productivity$_{US}$	0.41	41%
Investment Links + α avg.	0.62	62%
Only Domestic Investment Links	1.04	–

$$\ln(\mathbf{v}) = \underbrace{\Phi}_{\text{trade amplification}} \underbrace{\zeta'}_{\text{final-demand share}} \underbrace{(I - \Gamma\alpha\Omega^{Dom\prime} - (I-\Gamma)M')^{-1}}_{\text{augmented Leontief inverse}} \Gamma\mathbf{a}$$

→ Trade in capital goods: mild force for convergence (variance +4%).

avg. GDP p/cap. falls [60% – check] without capital-goods imports

income levels, no trade | full table

General Equilibrium

sectorial productivity growth & the investment network

Transition Dynamics: South Korea 1965–2014

- **Goal**: quantify role of sectorial productivity & Ω for output and capital accumulation
- 5 sectors: AGRI, CONS, ICT, MAN, SERV
- CES investment aggregator; elasticity ι estimated from Korean data, 1965–2014:

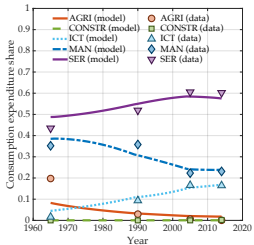

$$\ln\left(\frac{\omega_{int}}{\omega_{\text{MAN},nt}}\right) = \underbrace{\ln\left(\frac{\tilde{\omega}_{in}}{\tilde{\omega}_{\text{MAN},n}}\right)}_{\text{FE}_{in}} + (1-\iota)\ln\left(\frac{p_{it}}{p_{\text{MAN},t}}\right) + \varepsilon_{int} \quad \Rightarrow \quad \iota = 2.41$$

- loadings $\tilde{\omega}_{in,t}$ chosen so model & data investment expenditure shares coincide
- productivities calibrated to match relative prices & GDP per capita growth
- calibrated at four anchor years (1966, 1990, 2005, 2014); interpolated in between

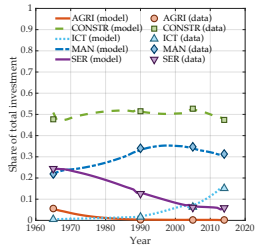

calibration | transition paths

Model Fit: Targeted Moments

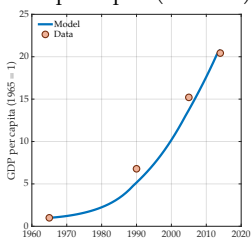

Sectoral Consumption Shares

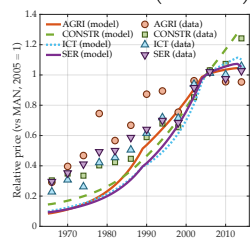

Sectoral Investment Shares

GDP per capita (1965 = 1)

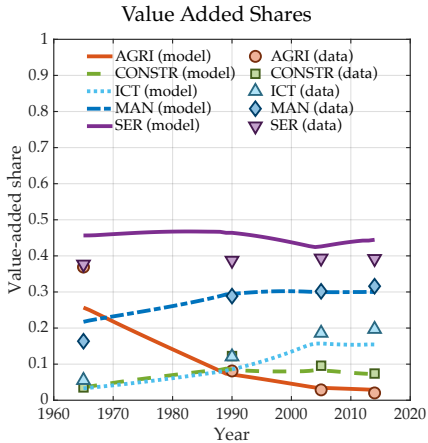

Relative Prices (2005 = 1)

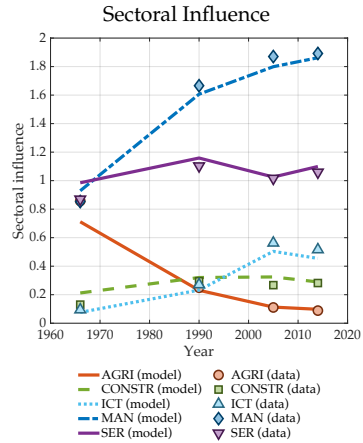

Model (lines) vs data (markers).

investment network by destination

Untargeted Moments: VA Shares & Sectoral Influence

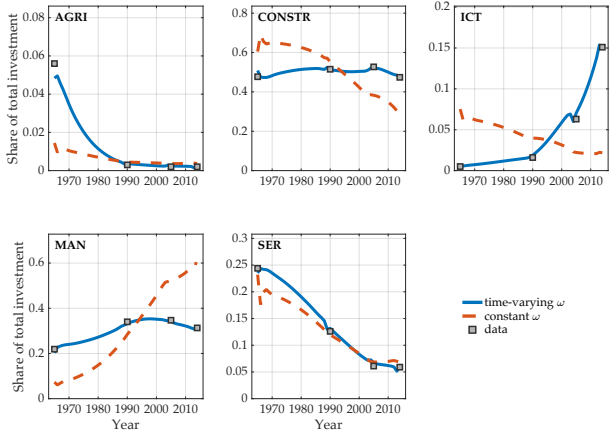

- MAN influence doubles ($\approx 0.9 \to 1.8$); ICT rises ($<0.2 \to \approx 0.6$); AGRI falls ($\approx 0.7 \to 0.1$)

transition paths: levels

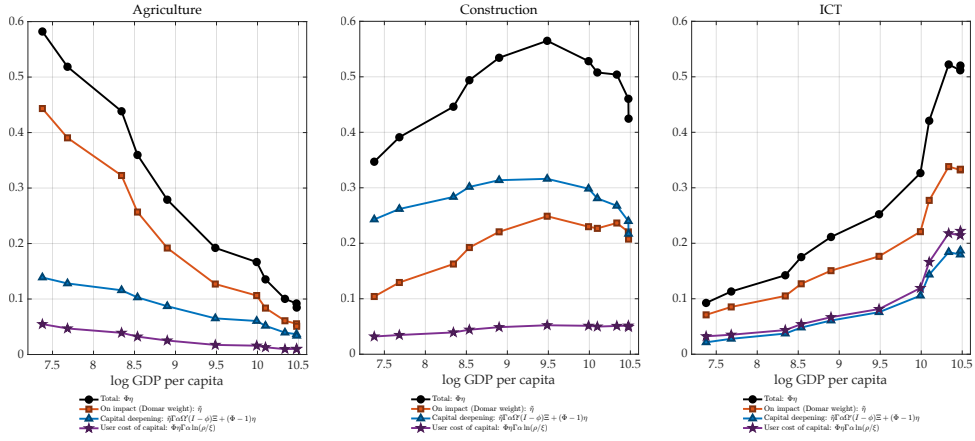

Counterfactual: the Role of Relative Prices for Changes in the Invest. Network

- Constant $\tilde{\omega}$: prices capture the fall of SERV ($\approx$25% $\rightarrow$ 5%), but miss the rise of ICT & CONS
- MAN share too low early (7% vs 22%) and too high late (60% vs 31%)

investment network, constant $\tilde{\omega}$

Channels of Sectoral Influence along Korea's Transition

MAN & SERV | shares of total

Counterfactual: the Role of the Investment Network

Scenario	$\Delta \ln Y$	$\Delta \ln(K/Y)$	$\frac{\Delta \ln Y}{\Delta \ln(K/Y)}$	$\Delta \ln Y - \frac{\bar{\alpha}}{1-\bar{\alpha}} \Delta \ln(K/Y)$	productivity % of $\Delta \ln Y$
Baseline	2.04	0.88	2.31	1.66	81%
Constant $\tilde{\omega}$	1.97	0.69	2.84	1.67	85%
Ω = KOR 1965	1.93	1.10	1.75	1.45	75%
Ω = value-added shares	1.92	0.87	2.20	1.54	80%
Ω = identity	2.04	0.69	2.98	1.74	85%

South Korea, 1965–2014. Detrended log changes, chained Törnqvist Y and K. Ω = VA shares uses a Cobb–Douglas investment aggregator ($\iota = 1$); others use $\iota = 2.41$. $\bar{\alpha}$: simple average of sectoral capital shares.

Illustrative economy (steady state): $$\frac{\Delta \ln \nu}{\Delta \ln(K/\nu)} = \frac{\alpha}{1-\alpha} + \frac{1}{1-\alpha} \frac{\sum_j \tilde{\eta}_j \, \Delta z_j}{\sum_j (\omega_j - \tilde{\eta}_j) \, \Delta z_j}$$

→ **Changes in the investment network** explain 24% ($= 1 - 1.75/2.31$) of the baseline variation in income from capital intensity

→ For comparison, at the average capital share $\bar{\alpha} = 0.30$: $\frac{\bar{\alpha}}{1-\bar{\alpha}} = 0.44$

no relative TFP growth

Final Remarks

- Sectoral influence w/ produced capital = **on impact** + **capital deepening**
  Domar weights depend on the transition path
- Build first **harmonized cross-country measures** of the investment network
- CONS & DUR matter through capital deepening; ICT rises with income through all channels
- Role for income disparities, $\approx 40\%$; heterogeneity in Ω reduces disparities
- MAN productivity growth key driver of KOR transition.
  Relative prices alone miss the evolution of Ω in some sectors.

Aggregate Growth Path

Proposition (AGP)

CD value added, CES aggregators from $\bar{t}$ on, investment inputs all substitutes (or all complements): asymptotic AGP where GDP and wages grow at constant rates. One sector n dominates investment; one sector n^* dominates final expenditure.

$$\hat{g}_w = \frac{(1-\phi_n)(\mathcal{A}g_z)_n + \phi_n \kappa_{n^*}(\mathcal{A}g_z)_{n^*}}{(1-\phi_n)\mathcal{B}_n + \phi_n\left[1-\kappa_{n^*}(1-\mathcal{B}_{n^*})\right]} \qquad g_Y = \kappa_{n^*}\left[(1-\mathcal{B}_{n^*})\hat{g}_w + (\mathcal{A}g_z)_{n^*}\right]$$

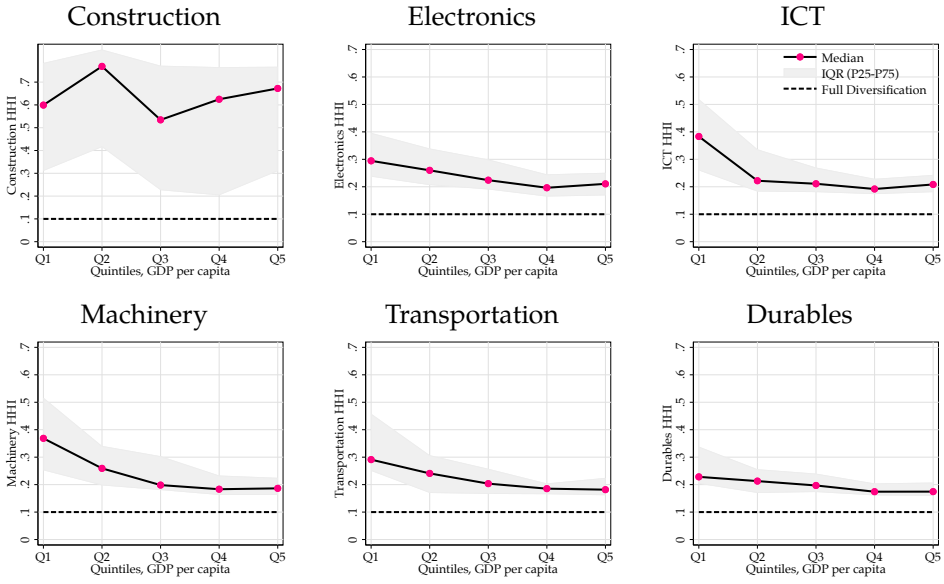

$$g_{p_j^x} = g_{R_j} = g_Y - \hat{g}_w, \qquad g_{k_j} = \hat{g}_w + g_{l_j}$$

$\hat{g}_w \equiv g_W - g_{p_n^x}$; $\mathcal{A} \equiv \Psi\Gamma^\infty$, $\mathcal{B} \equiv \mathcal{A}(I-\alpha)\mathbf{1}$ (embodied labor share), Ψ Leontief inverse, $\kappa_{n^*} \equiv \frac{\sigma-1}{\sigma-\epsilon_{n^*}}$

closed economy: $\hat{g}_w = \frac{(\mathcal{A}g_z)_n}{\mathcal{B}_n}$ (1 sector: $g_z/(1-\alpha)$)

back

Investment network: HHI demand for investment

back

Welfare

Proposition (Welfare)

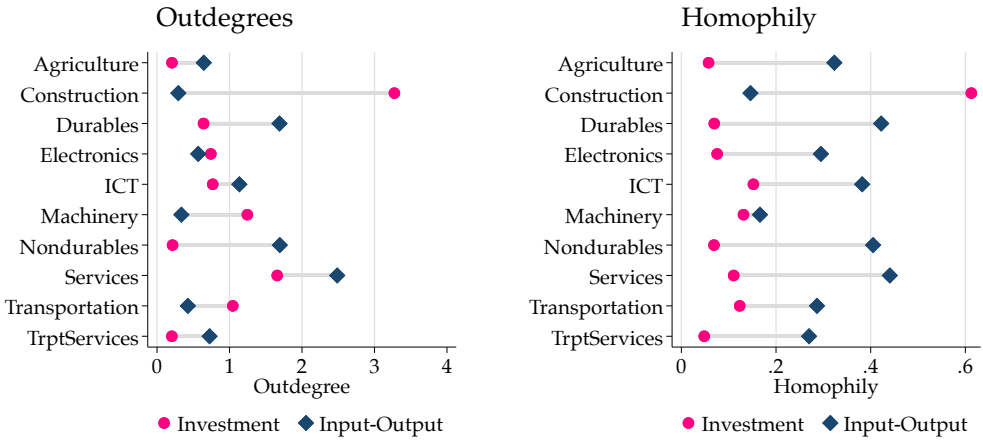

$$\textit{Welfare influence} \equiv \frac{d \ln C_t}{d \ln z_{nt}} = \underbrace{\overbrace{\frac{p_t v_t}{C_t}}^{GDP}}_{cons.} \tilde{\eta}_{nt} \gamma_{nt}$$

$$\tilde{\eta}_t = \underbrace{[I - (I - \phi)\Omega_t \Gamma_t \alpha_t \rho_t - M_t(I - \Gamma_t)]^{-1}}_{augmented\ Leontief\ inverse} \underbrace{\tilde{\zeta}_t}_{final\ uses}$$

envelope theorem; GDP/C constant along AGP → amplified or dampened along the transition
